

## 1. Function and Use.

This small program will convert SJIS encoded Japanese characters into a ‘preprocessed’ form. The need of this program arises from the fact that this encoding uses the characters ‘\’, ‘{’, and ‘}’ which have special meanings in T<sub>E</sub>X.

Use this program as a filter:

```
sjisconv < input_file > output_file
```

## 2. The program.

The only function of this program is to replace all occurrences of SJIS encoded two byte characters XY with  $\text{^7f}X\text{^7f}ZZZ\text{^7f}$  (X and Y are the first and the second byte of the character; ZZZ represents the second byte as a decimal number).

Additionally we define a  $\text{\TeX}$  macro at the very beginning to signal a preprocessed file.

The following code is very simple. No error detection is done because  $\text{\TeX}$  which will see the output of `sjisconv` complains loudly if something is wrong.

```
#define banner "sjisconv_(CJK_ver._4.6.0)"

#include <stdio.h>
#include <stdlib.h>

int main(argc, argv)
    int argc;
    char *argv[];
{int ch;

fprintf(stdout, "\\def\\CJkpreproc{\\%s}", banner);
ch = fgetc(stdin);

while (!feof(stdin))
{if ((ch >= #81 & ch <= #9F) <(ch >= #E0 & ch <= #EF))
 {fprintf(stdout, "\\177%c\\177", ch);

ch = fgetc(stdin);
if (!feof(stdin))
fprintf(stdout, "%d\\177", ch);
}

else
fputc(ch, stdout);
ch = fgetc(stdin);
}
exit(EXIT_SUCCESS);
return 0;                                /* never reached */
}
```
